

1 **Guidelines for Inspection, Repair, and Use of Portable Concrete Barriers**

2

3 In October of 2019, The Federal Highway Administration (FHWA) and the Texas Department of  
4 Transportation Research and Technology Implementation Office sponsored research on the  
5 Development of Guidelines for Inspection, Repair, and Use of Portable Concrete Barriers. Texas A&M  
6 Transportation Institute (TTI) conducted full-scale testing and calibrated computer simulations on  
7 several different types, shapes and sizes of reinforced concrete traffic barriers to define inspection  
8 criteria for assessment and to verify that current typical barrier types meet the latest AASHTO criteria  
9 for crashworthiness.

10 The researchers conducted both virtual and physical tests, using instrumented test vehicles and full-size  
11 trucks to validate a parametric computer model using Finite Element Analysis (FEA). While the tests  
12 were conducted on specific sizes and types of barriers, the results of the research, published in  
13 September 2022, may be applied to any size and shape of reinforced concrete barrier currently being  
14 produced in the United States.

15 While damage assessment of existing concrete traffic barriers is necessarily the responsibility of the  
16 owner or owner’s engineer, the purpose of this research was to categorize different types of damage  
17 and to provide a uniform set of evaluation criteria to provide guidance for inspection and assessment  
18 based on results of both the parametric and physical tests.

19 In assessing damaged barrier sections, three types of damage are identified: spalls, cracks and  
20 connections. For each damage type, varying degrees of damage are classified as either acceptable,  
21 acceptable with repair, or unacceptable.

22 **Spalling**

23 The first type of damage is spalled concrete. Spalls of nearly any size are acceptable as long as no  
24 reinforcement is exposed, all unsound concrete in the area of the spall has been removed and cracking  
25 around the damaged area is kept to within specified limits (Figure 1). If the reinforcing steel is exposed  
26 and either has very little corrosion or no corrosion at all, then the barrier is deemed acceptable with  
27 repair. However, once any exposed reinforcing has begun to show signs of corrosion beyond a light red  
28 dust, regardless of whether it would affect the performance of the barrier, the barrier is deemed  
29 unacceptable and should be removed from service.

30

31

32

### 33 Cracking

34 “Hairline” cracks (<0.003 in.) are acceptable without repair, regardless of length or number. A single  
 35 crack no wider than ¼ in. or multiple cracks whose cumulative widths do not exceed ¼ in. within a 1 ft.  
 36 longitudinal length of the barrier segment must be repaired, and once repaired, the barrier is acceptable  
 37 for use. No width threshold is given for cracks needing repair, because cracks were not included as part  
 38 of the parametric model. A practical crack width for consideration would be between 3/16 in. and ¼ in.  
 39 before repairing. The direct reference to a ¼ in. crack width in the report comes straight from the  
 40 physical tests in which a barrier section with a single ¼ in. wide crack at the point of impact was  
 41 evaluated. The cracked barrier performed well, and the test vehicle did not deform past allowable  
 42 limits. But the researchers determined that no further conclusions regarding crack widths could be  
 43 drawn from the test data.

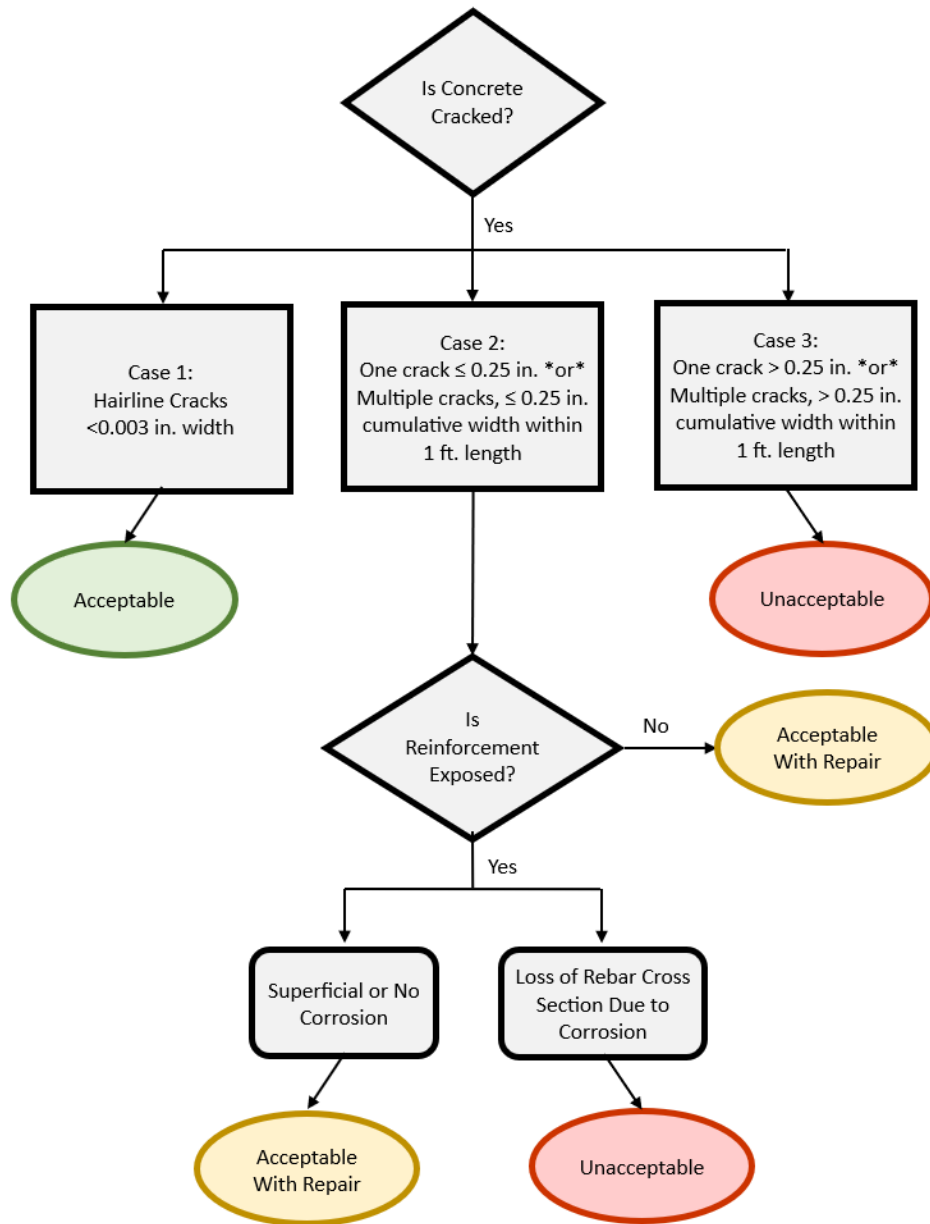

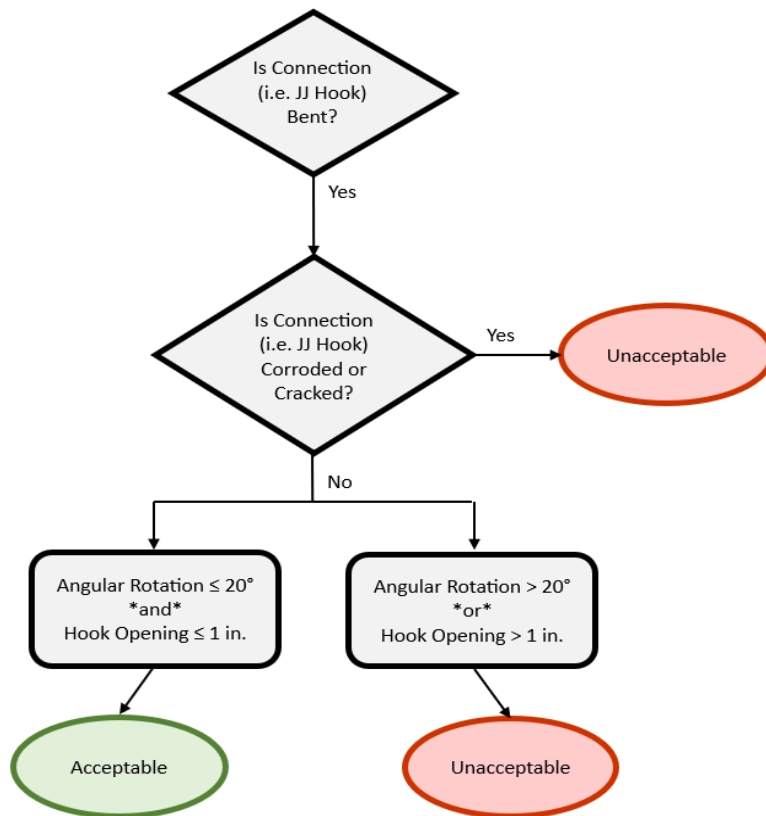

Figure 2: Cracking Evaluation Criteria Flowchart

44  
45  
46

47 The report makes no reference to the direction of the cracks in the barrier. Longitudinal cracks  
 48 occurring along the length of the barrier are therefore treated the same as vertical cracks. The total  
 49 length of the crack is also not addressed, just that all portions of one or more cracks appearing in any 1  
 50 ft. length of a barrier segment are the subject of evaluation. Should any one of those cracks, or the sum  
 51 of multiple cracks occurring within a 1 ft. segment of barrier length, be greater than ¼ inches in width,  
 52 then the barrier is unacceptable for repair and must be removed from service. As with spalling, if the  
 53 cracks are small enough to repair but the steel reinforcement has been exposed and has begun to  
 54 corrode, then the barrier section is unacceptable.

55 **Connections**

56 For damage to barrier connections, two main types of connections are addressed, with different  
57 recommendations given for each. For the “JJ Hook” connection, where embedded steel plates are  
58 fabricated in a hook shape so that they interlock at the connection, the maximum amount of rotation in  
59 the plane of the hook is 20°. Moreover, the opening inside the hook must not have been pried open  
60 more than 0.1 inch so that the entire hook opening does not exceed 1 inch, otherwise the barrier is  
61 unacceptable as best can be determined from the report. Any amount of corrosion or cracking in the JJ  
62 Hook is also unacceptable. No provision is made for straightening or reforming the steel hook plate,  
63 even if no corrosion or cracking in the steel is observed and there is no gap in the connection.

64

65

66

**Figure 3: Connection Evaluation Criteria Flowchart**

67 For bolted connections made with “Quick Bolts”, “X-Bolts” or other types of bolted connections, there  
68 must not be any missing, deformed, cracked or corroded bolting hardware or cracks of any width in the  
69 concrete around embedded hardware, otherwise the barrier is unacceptable.

70 All barrier segments impacted during the course of this research study reportedly met all the  
71 performance criteria of AASHTO MASH Test 3-11. Since all physical tests were performed on full-scale  
72 existing barrier shapes and designs, precast barriers manufactured prior to the year 2020, the year  
73 AASHTO MASH was implemented, that meet the assessment criteria contained in this report are  
74 acceptable for continued use throughout their intended service life – and beyond.
